

3. Project Design Phase

1. Introduction

The Project Design Phase defines how the Auto Ticket Classification system will be built and how its different components will work together. The main goal is to automatically classify incoming support tickets and route them to the appropriate category, priority, and assignment group.

2. System Design

Input → Ticket Analysis → Classification → Assignment → Notification

Ticket Creation

A user creates a support ticket with details such as short description, description, category, and priority.

Ticket Analysis

The system reads the ticket information and identifies important keywords and patterns.

Automatic Classification

The ticket is classified into a suitable category, such as:

Hardware

Software

Network

Access/Login

Database

Assignment

Based on the classification, the ticket is automatically assigned to the appropriate support group.

Notification

The assigned team receives a notification about the new ticket.

3. Main Components

ServiceNow Incident Table – Stores ticket information.

Flow Designer – Automates the classification and assignment process.

Classification Logic – Determines the ticket category based on its content.

Assignment Rules – Selects the appropriate support group.

Notification System – Sends alerts to the responsible team.

Reporting/Dashboard – Displays ticket classification and processing status.

4. Example

Ticket: “Unable to connect to Wi-Fi.”

Process:

New Ticket → Analyze Description → Network Category → Network Support Group
→ Notification

5. Expected Result

The design reduces manual ticket handling, improves assignment accuracy, speeds up ticket processing, and ensures that tickets reach the appropriate support team quickly.
